Objective

Measurement Type

Site Characterization: One time sampling

Site Characterization: One time		1			
Soil Samples	To determine if	50 soil samples	\$50 to \$250		
(http://www.gmslab.com)	the area	taken in evenly	per sample		
lead, chromium, arsenic, zinc,	surrounding the	spaced	Total=		
cadmium, copper, mercury and	waste transfer	transects	\$10,000		
nickel	station	radiating from			
	experiences	the waste			
	higher than	transfer station.			
	average heavy				
	metal				
	concentrations				
Stationary Monitoring: Permane	ntly installed monito	oring stations to cap	oture the daily,		
weekly and annual cycle of pollutants of interest. Measurements are taken					
continuously and can be utilized to determine periods and locations of high pollutant					
concentrations.					
AQMESH Air Sensors	To determine if	12 Station	\$15,000 per		
(http://www.aqmesh.com)	the area	locations:	station		
Nitric oxide, Nitrogen dioxide,	surrounding the	North, East,			
Ozone, Temperature,	waste transfer	West and South	Total =		
Atmospheric pressure, Relative	station	boundaries of	\$180,000		
humidity, Particle count,	experiences	facility.	-25%		
Particulate Matter 2.5 microns,	higher than	Four additional	discount =		
Particulate Matter 10 microns,	average air	stations one	\$135,000		
Carbon monoxide, Sulphur	pollutant	block from			
dioxide	concentrations	operations in	Ongoing		
		each direction.	replacement		
		1 station in	cost		
		Mason Park	\$2,000 per		
		1 station at	year		
		ETHS			
		2 control	Total =		
		stations in	\$24,000		
		similar trafficked			
		locations in			
		Evanston (e.g.			
		Dempster,			
		Emerson)			

Mobile Sensors: Mobile sensors allow for the quantification of an individual's exposure to an air pollutant (Exposure = Time x concentration). Additionally, mobile sensors engage the community in process of monitoring the areas air quality facilitating the transfer of results back to the community.

Air Beam Particulate Matter 2.5	To access the level of exposure to particulate matter of a resident in the vicinity of the waste transfer station.	50 units distributed to residents of the area and high school students.	\$250 per unit Total = \$12,500
SPME Fibers (http://www.sigmaaldrich.com) Volatiles, trace compound analysis, organic compounds	To determine the chemical constituents of the odor generated at the waste transfer station	20 Fibers: Fibers can be utilized to sample air during high odor days. Fibers are reusable and will be distributed to residents in the vicinity of the waste transfer station.	\$500 per unit Total = \$10,000

A review of the available literature identified the following potential pollutants associated with waste transfer stations:

- Heavy metals (e.g. Lead, Mercury) generated by the improper disposal of lightbulbs, batteries and electronics.
- Organic compounds released during decomposition
- Vehicle pollutants (e.g. Nitrogen dioxide, carbon monoxide) due to increased large vehicle traffic
- Particulate matter generated during transfer operations.

The following sensors and sampling techniques are recommended to characterize and monitor the levels of pollution being generated.
